

# RECURSION ON NON- NUMERICS

(download slides and .py files to follow along)

6.100L Lecture 16

Ana Bell

# REVIEW OF RECURSION FROM LAST LECTURE, WITH AN EXAMPLE

- Fibonacci numbers (circa 1202)
- Leonardo of Pisa (aka Fibonacci) modeled rabbits mating (under certain assumptions) as a Fibonacci sequence
  - newborn pair of rabbits (one female, one male) are put in a pen
  - rabbits mate at age of one month
  - rabbits have a one month gestation period
  - assume rabbits never die, that female always produces one new pair (one male, one female) each month from its second month on
- $\text{females}(n) = \text{females}(n-1) + \text{females}(n-2)$

↑  
Females alive in  
month n-1

↑  
Every female alive at  
month n-2 will produce  
one female in month n

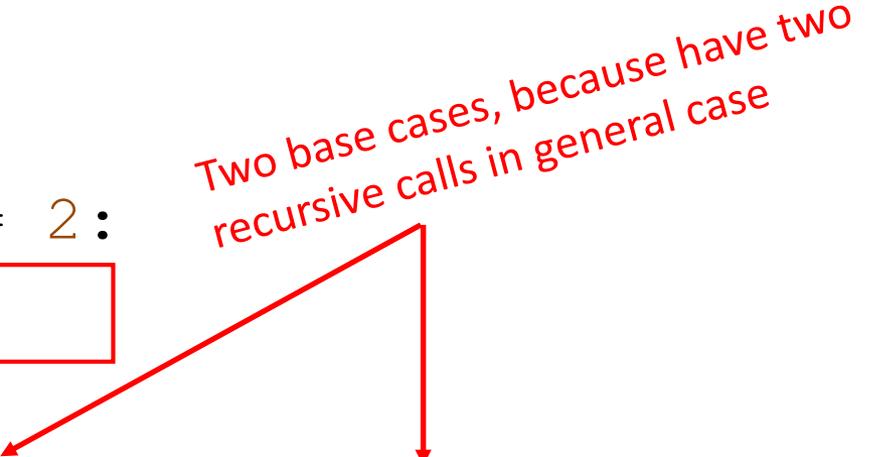

Month	Females
1	1
2	1
3	2
4	3
5	5
6	8
7	13

# FIBONACCI

- Base cases:
  - Females(1) = 1
  - Females(2) = 1
- Recursive case
  - Females(n) = Females(n-1) + Females(n-2)

# FIBONACCI RECURSIVE CODE (MULTIPLE BASE CASES)

```
def fib(x):  
    if x == 1 or x == 2:  
        return 1  
    else:  
        return fib(x-1) + fib(x-2)
```

Two base cases, because have two recursive calls in general case

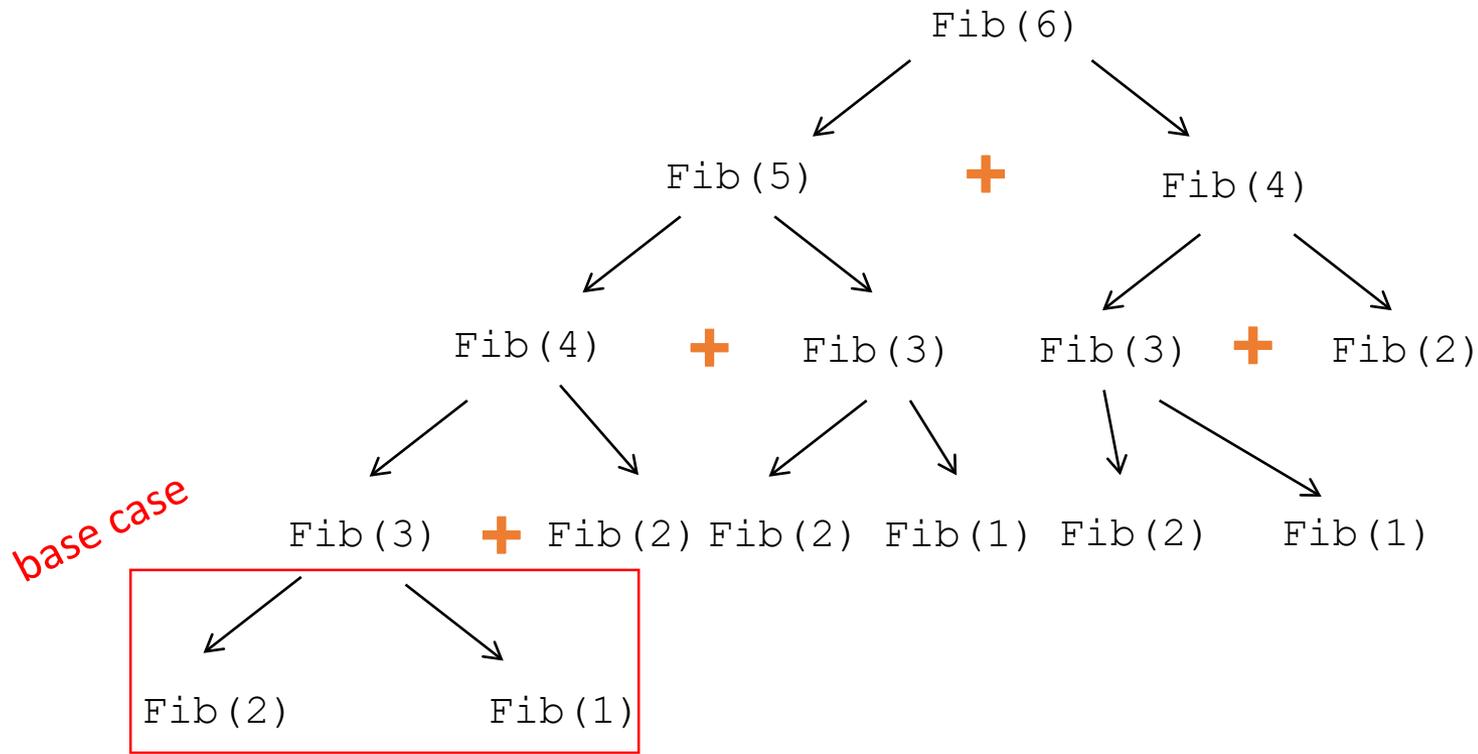

## Two base cases

- Calls itself twice
- But! It has to go to the **base case of the first fib call** before completing the second fib call

# HIGH-LEVEL VIEW OF FIBONACCI with RECURSION

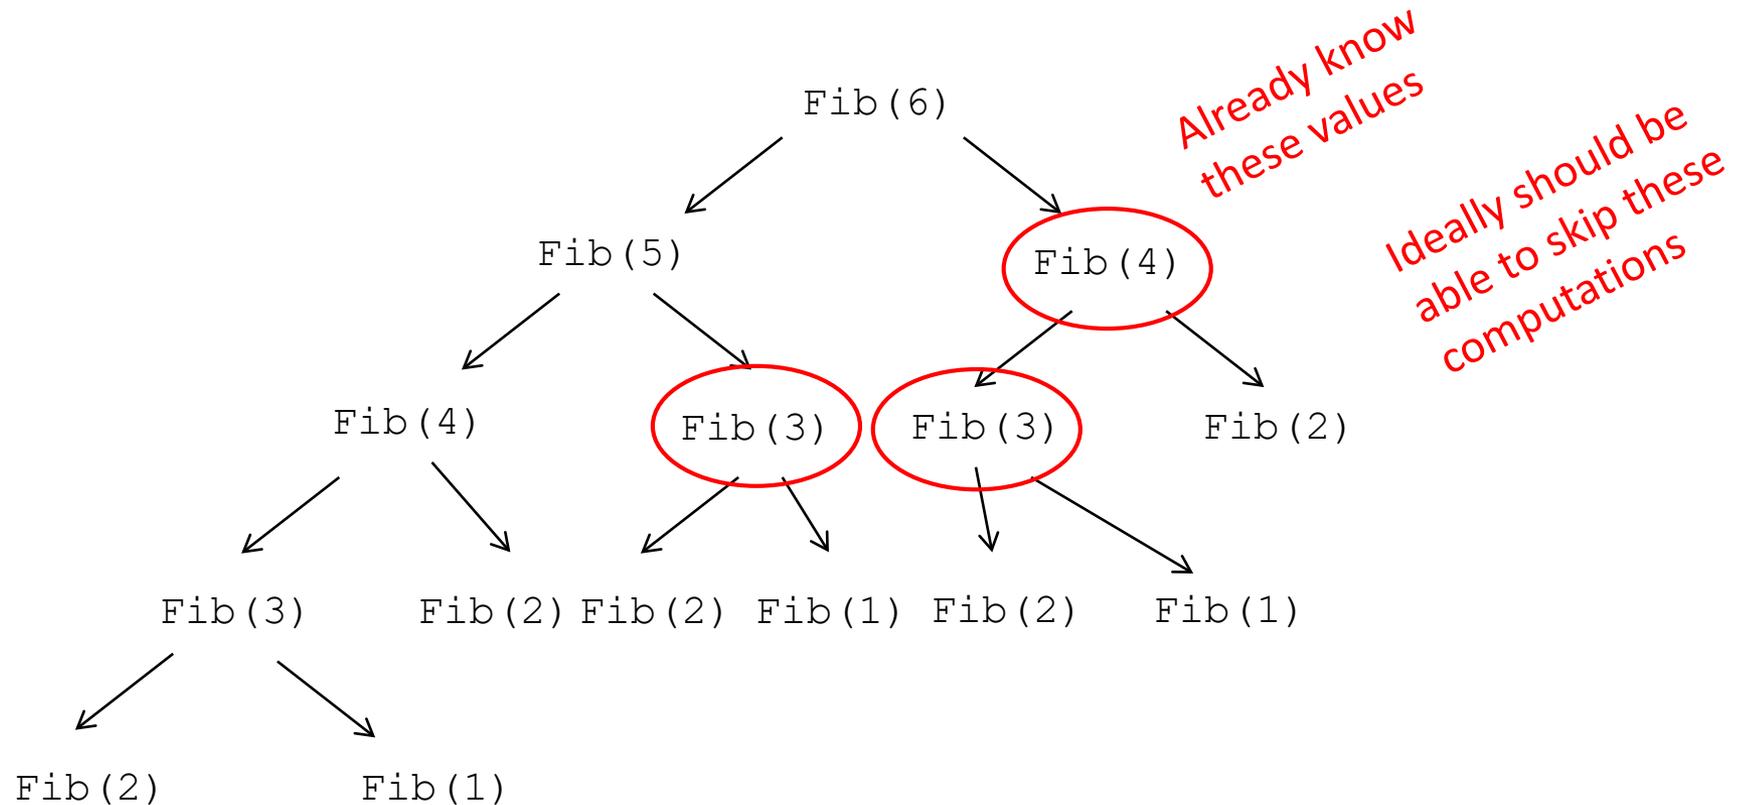

[PYTHON TUTOR LINK](#)

```
def fib(x):  
    if x == 1 or x == 2:  
        return 1  
    else:  
        return fib(x-1) + fib(x-2)
```

# INEFFICIENT FIBONACCI

$$\text{fib}(x) = \text{fib}(x-1) + \text{fib}(x-2)$$

- **Recalculating** the same values many times!
- Could keep **track** of already calculated values

# FIBONACCI WITH MEMOIZATION

[Python Tutor LINK](#)

```
def fib_efficient(n, d):
```

```
    if n in d:  
        return d[n]
```

Before recursively finding  
Fibonacci, check if we  
already have the value

```
    else:
```

```
        ans = fib_efficient(n-1, d) + fib_efficient(n-2, d)
```

```
        d[n] = ans
```

```
    return ans
```

Calculate it  
Add to dictionary

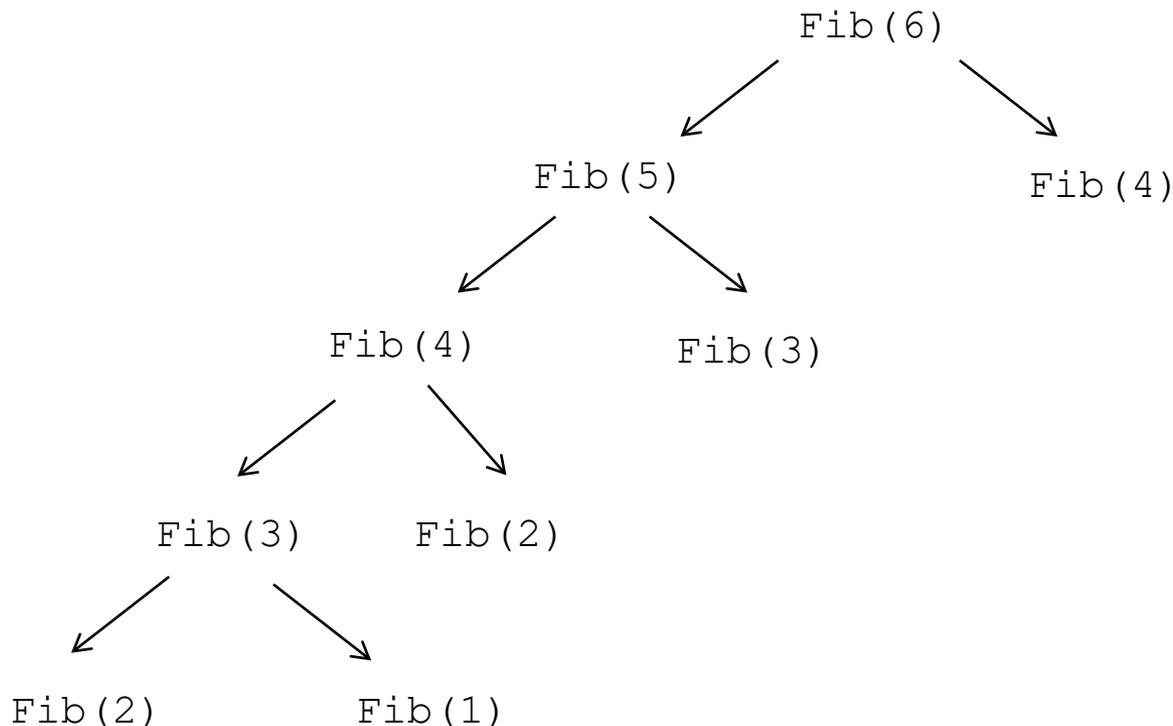

```
d = {1:1, 2:1}
```

```
print(fib_efficient(6, d))
```

Initialize dictionary  
with base cases

- Do a **lookup first** in case already calculated the value
- **Modify dictionary** as progress through function calls

# EFFICIENT FIBONACCI CHECKS the DICT FIRST

n	fib(n)
1	1
2	1
3	2
4	3
5	5
6	8

- **No more recalculating**, just check the dict before calculating!
- Add to the dict so we can **look it up next time** we see it

# EFFICIENCY GAINS

- Calling `fib(34)` results in **11,405,773** recursive calls to the procedure
- Calling `fib_efficient(34)` results in **65** recursive calls to the procedure
- Using dictionaries to capture intermediate results can be very efficient
- But note that this only works **for procedures without side effects** (i.e., the procedure will always produce the same result for a specific argument independent of any other computations between calls)

# A MORE PRACTICAL EXAMPLE

WHAT ARE ALL THE WAYS YOU CAN MAKE A SCORE OF  $x$  IN BASKETBALL?

```
def score_count(x):  
    """ Returns all the ways to make a score of x by adding  
    1, 2, and/or 3 together. Order doesn't matter. """
```

```
if x == 1:  
    return 1
```

```
elif x == 2:  
    return 2
```

```
elif x == 3:  
    return 3
```

Score of 1 made with:  
1+0

Score of 2 made with:  
1+1 or 2+0

Score of 3 made with:  
1+1+1 or 2+1 or 3+0

In basketball you can make a basket worth 1, 2, or 3 points

- Base cases: **3 of them!**
  - You can make a score of 1 with 1+0 (that's 1 way)
  - You can make a score of 2 with 1+1 or 2+0 (that's 2 ways)
  - You can make a score of 3 with 1+1+1 or 2+1 or 3+0 (that's 3 ways)

# A MORE PRACTICAL EXAMPLE: [PYTHON TUTOR LINK](#)

WHAT ARE ALL THE WAYS YOU CAN MAKE A SCORE OF  $x$  IN BASKETBALL?

```
def score_count(x):  
    """ Returns all the ways to make a score of x by adding  
    1, 2, and/or 3 together. Order doesn't matter. """  
    if x == 1:  
        return 1  
    elif x == 2:  
        return 2  
    elif x == 3:  
        return 3  
    else:  
        return score_count(x-1) + score_count(x-2) + score_count(x-3)
```

*All ways to make a score of  $x-1$*

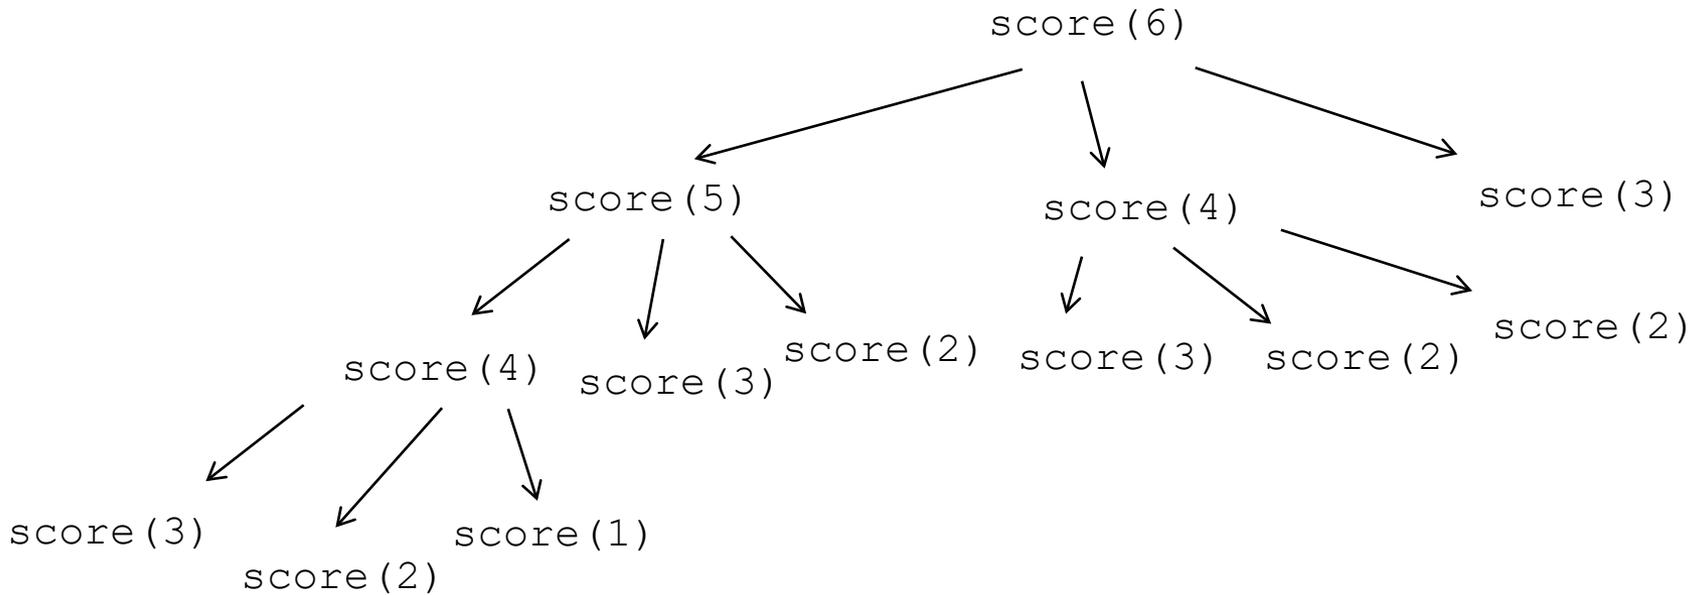

*All ways to make a score of  $x-2$*

*All ways to make a score of  $x-3$*

- Recursive step: Let **future function calls do the work** down until base cases
  - Ways to make a score of  $x$  means you could have made:  
a score of  $(x-1)$  or a score of  $(x-2)$  or a score of  $(x-3)$
  - If you make a score of  $x-1$  you can just add 1 to it to make the score of  $x$ .
  - If you make a score of  $x-2$  you can just add 2 to it to make the score of  $x$ .
  - If you make a score of  $x-3$  you can just add 3 to it to make the score of  $x$ .

# HIGH-LEVEL VIEW of score\_count

```
def score_count(x):  
    if x == 1:  
        return 1  
    elif x == 2:  
        return 2  
    elif x == 3:  
        return 3  
    else:  
        return score_count(x-1)+score_count(x-2)+score_count(x-3)
```

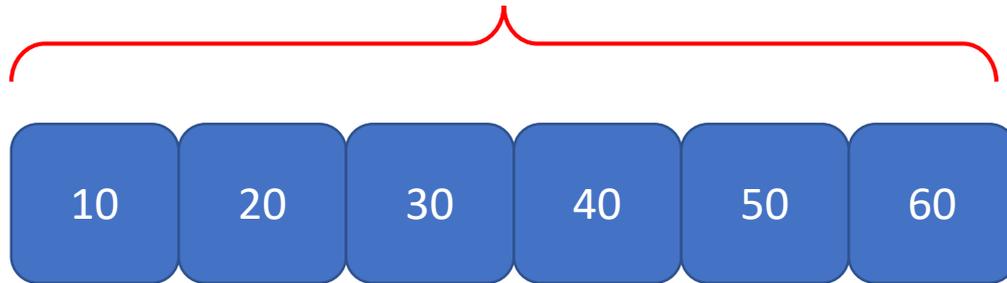

# SUM of LIST ELEMENTS

# LISTS ARE NATURALLY RECURSIVE

```
def total_iter(L):  
    result = 0  
    for e in L:  
        result += e  
    return result  
  
test = [30, 40, 50]  
print(total_iter(test))
```

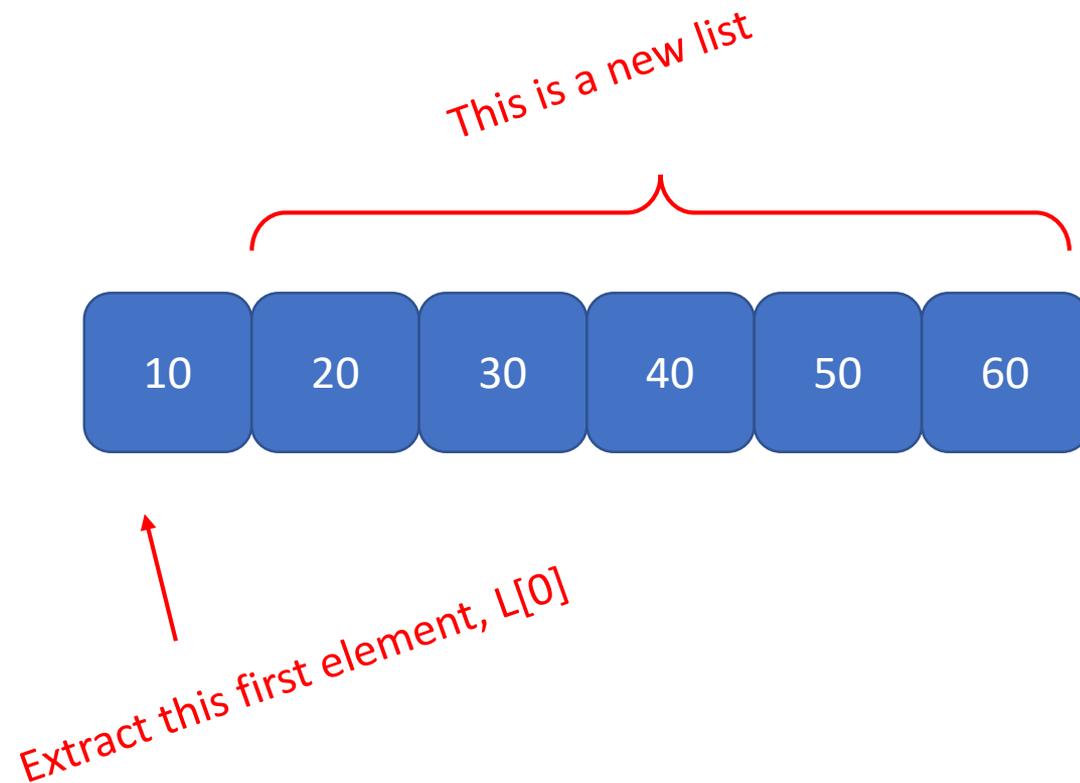

# VISUALIZING LISTS as RECURSIVE

*This is your original list*

- Find sum of this original list

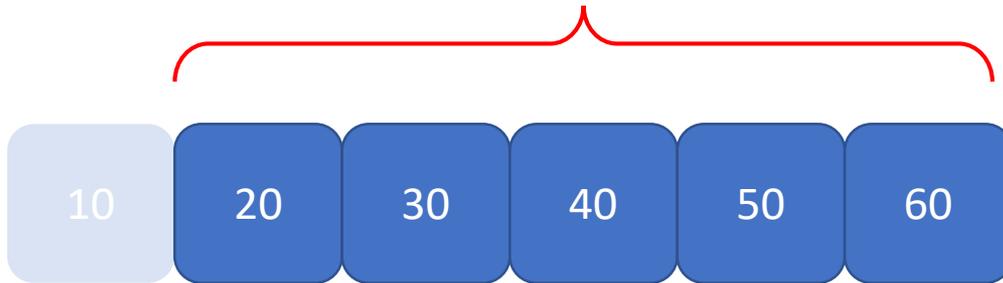

# VISUALIZING LISTS as RECURSIVE

- $L[0]$  + sum of the new list

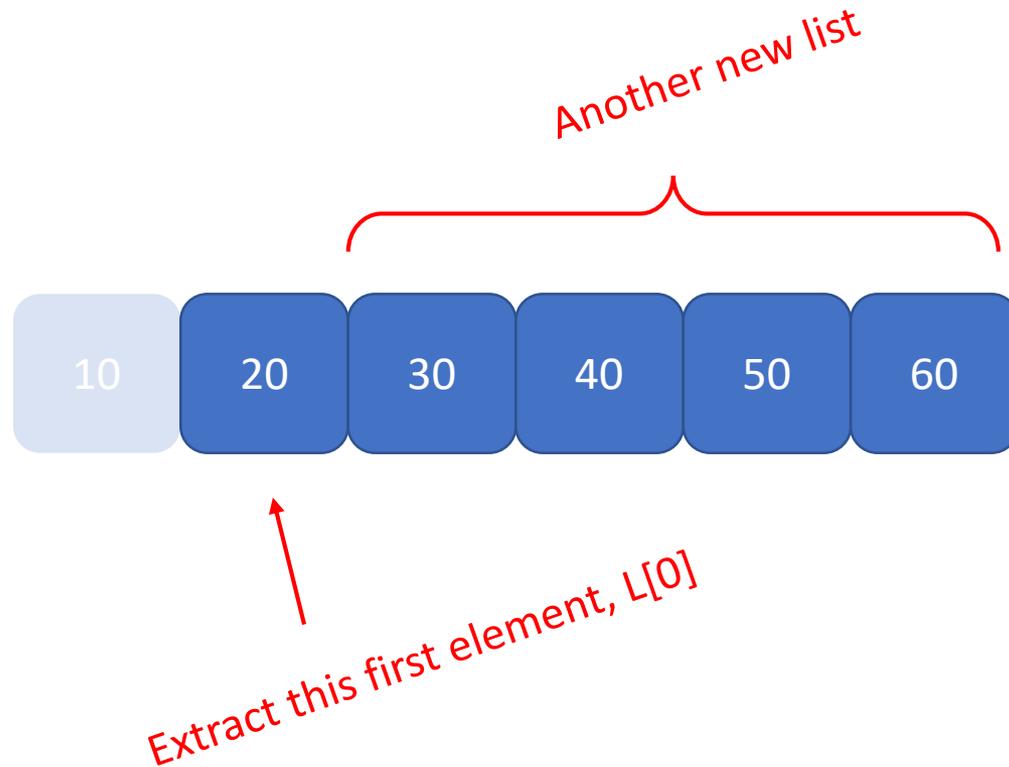

# VISUALIZING LISTS as RECURSIVE

*This is a list you can do the same operations on as before*

- Solve the same problem, slightly changed (its length is smaller)

# VISUALIZING LISTS as RECURSIVE

- $L[0]$  + sum of the new list

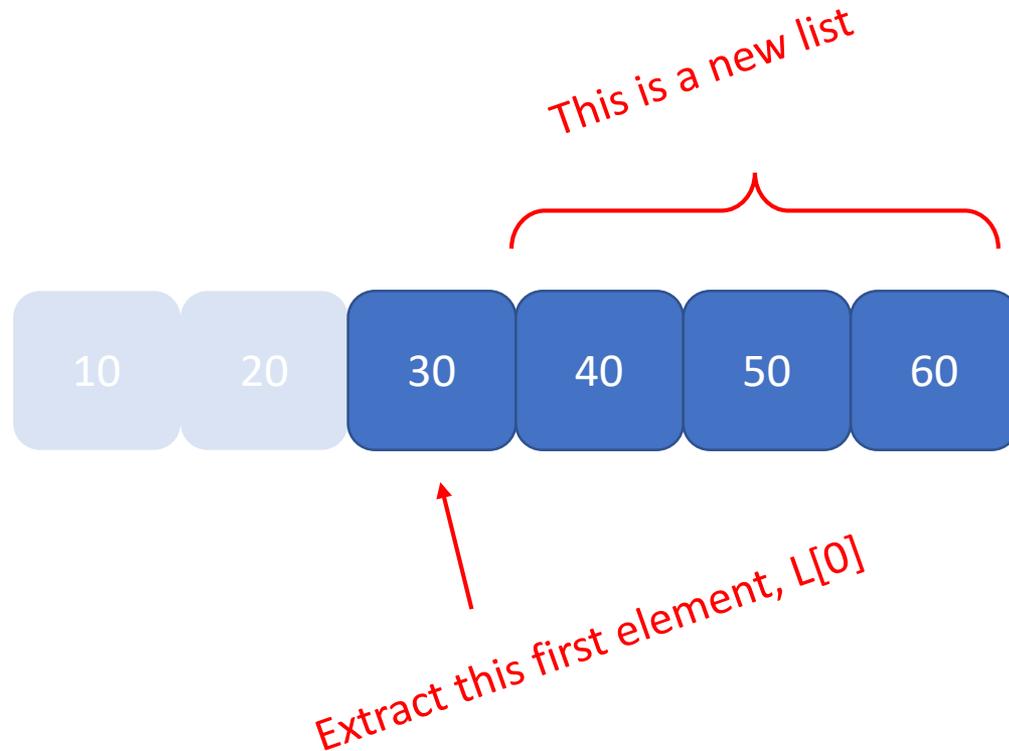

# VISUALIZING LISTS as RECURSIVE

*Another new list you can do  
the same operations on*

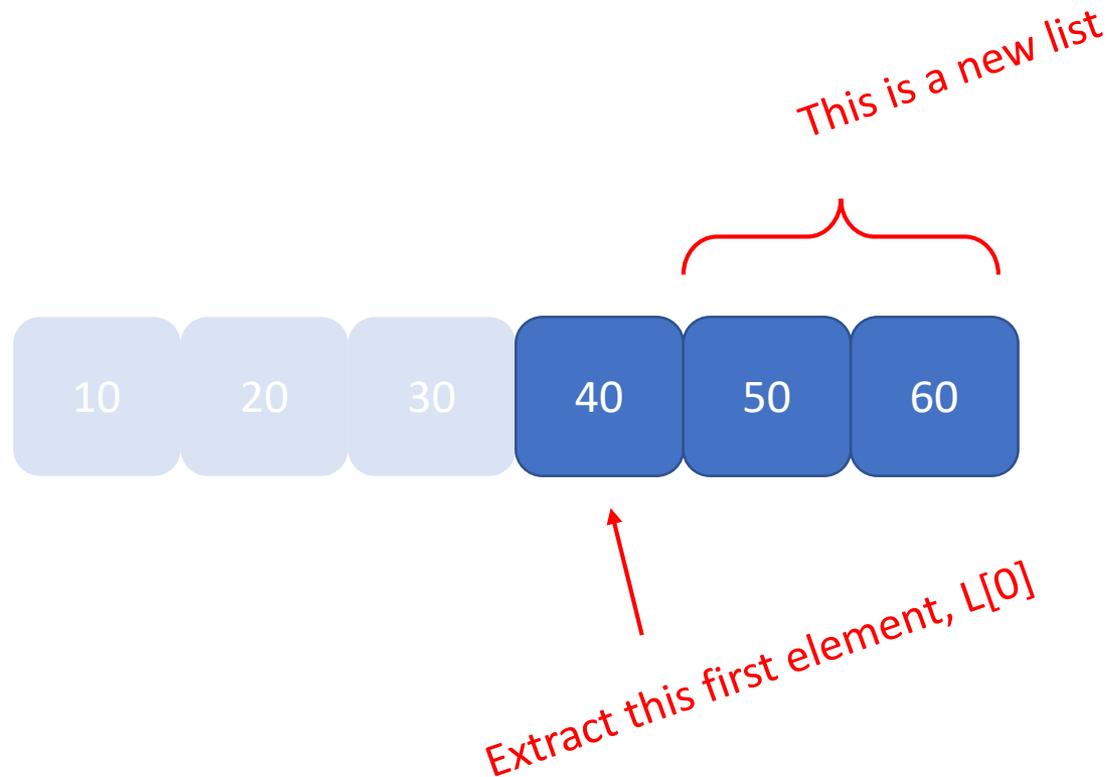

- Solve the same problem again, slightly changed

# VISUALIZING LISTS as RECURSIVE

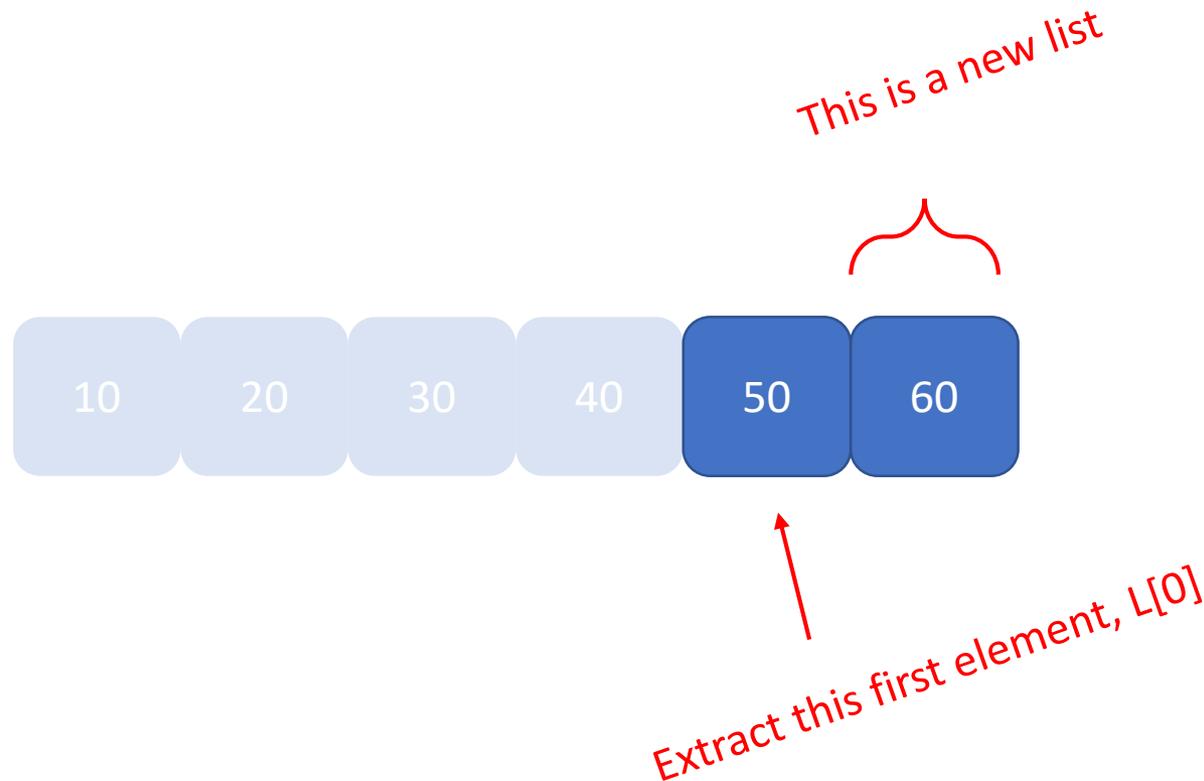

- $L[0]$  + sum of the new list

# VISUALIZING LISTS as RECURSIVE

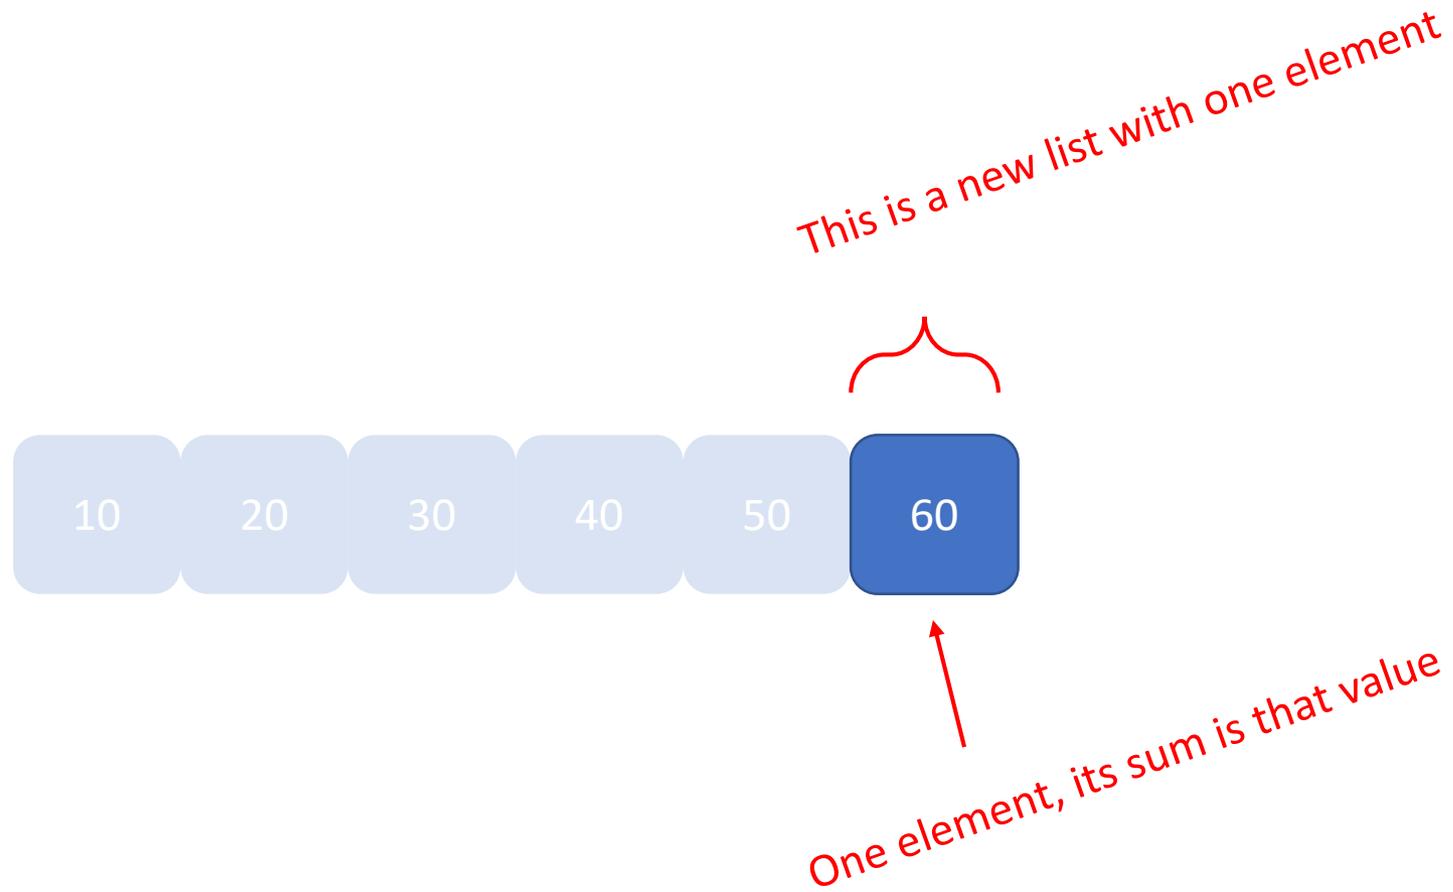

- Keep repeating, decreasing until a base case

# VISUALIZING LISTS as RECURSIVE

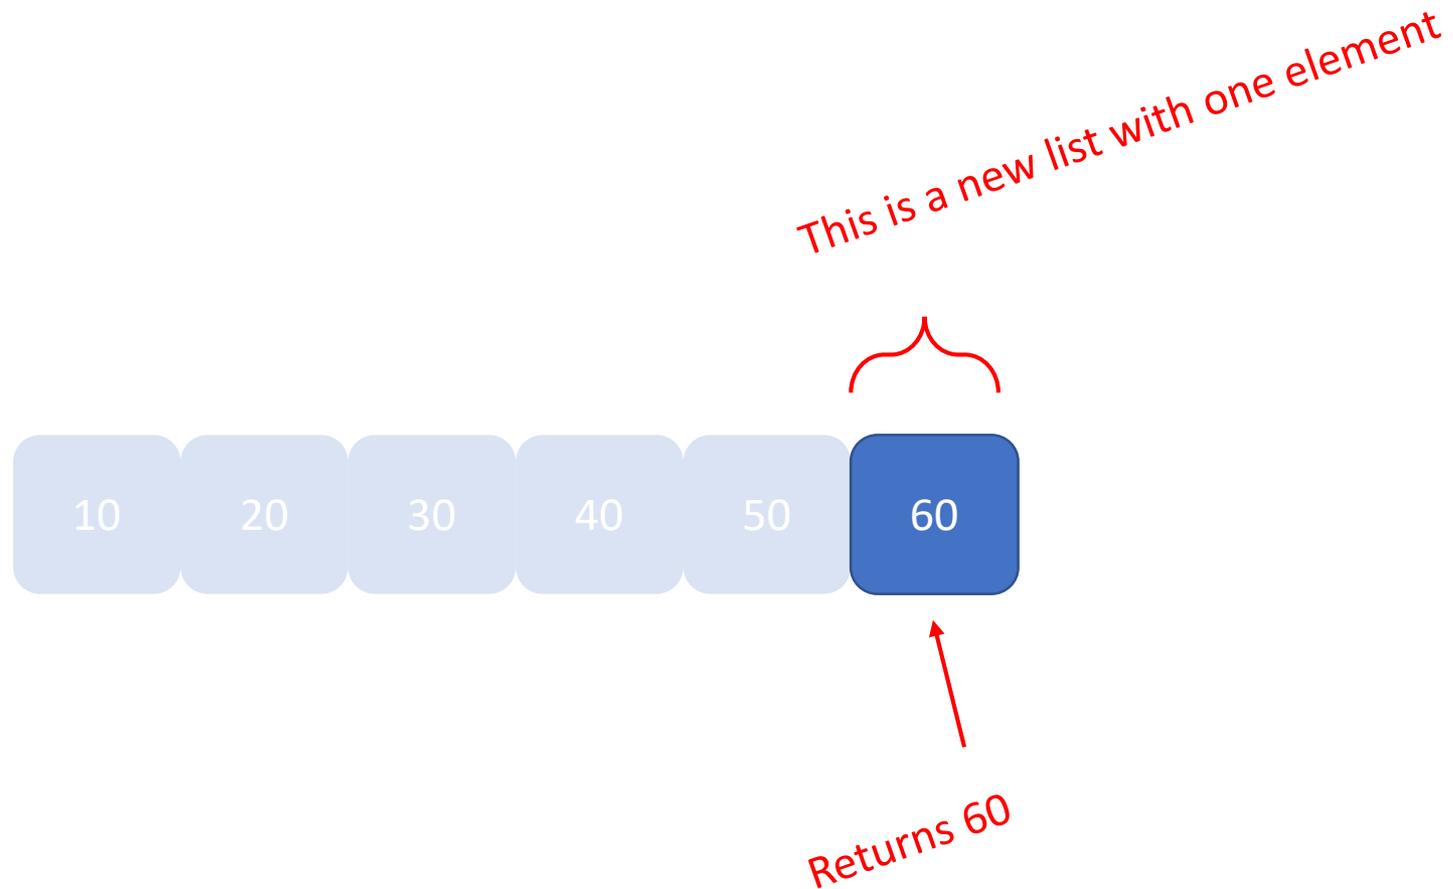

- Keep repeating, decreasing until a base case

# VISUALIZING LISTS as RECURSIVE

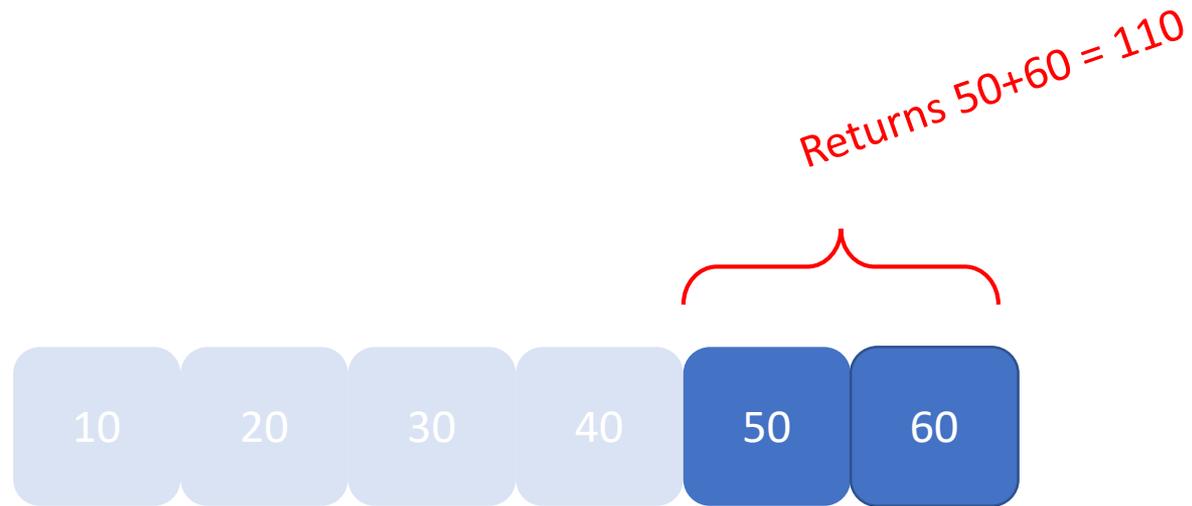

- The base case

# VISUALIZING LISTS as RECURSIVE

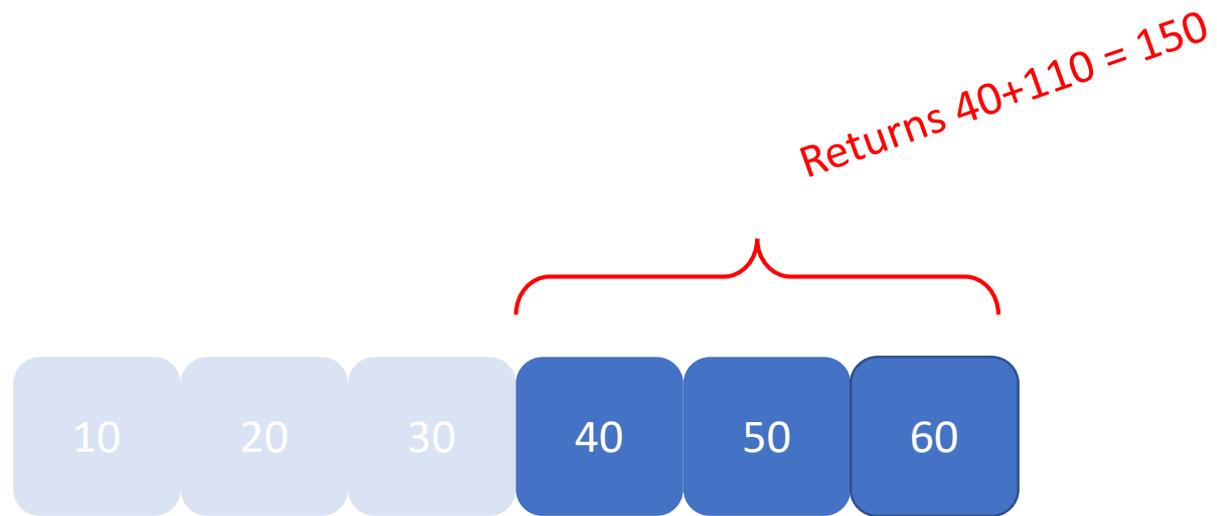

- Pass the sum back up the chain

# VISUALIZING LISTS as RECURSIVE

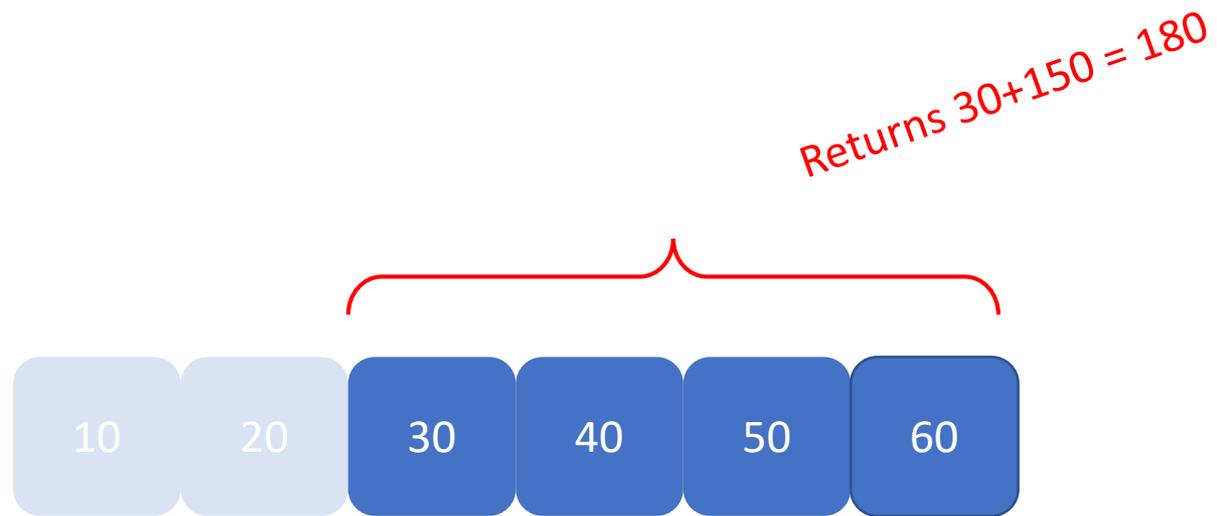

- Pass the sum back up the chain

# VISUALIZING LISTS as RECURSIVE

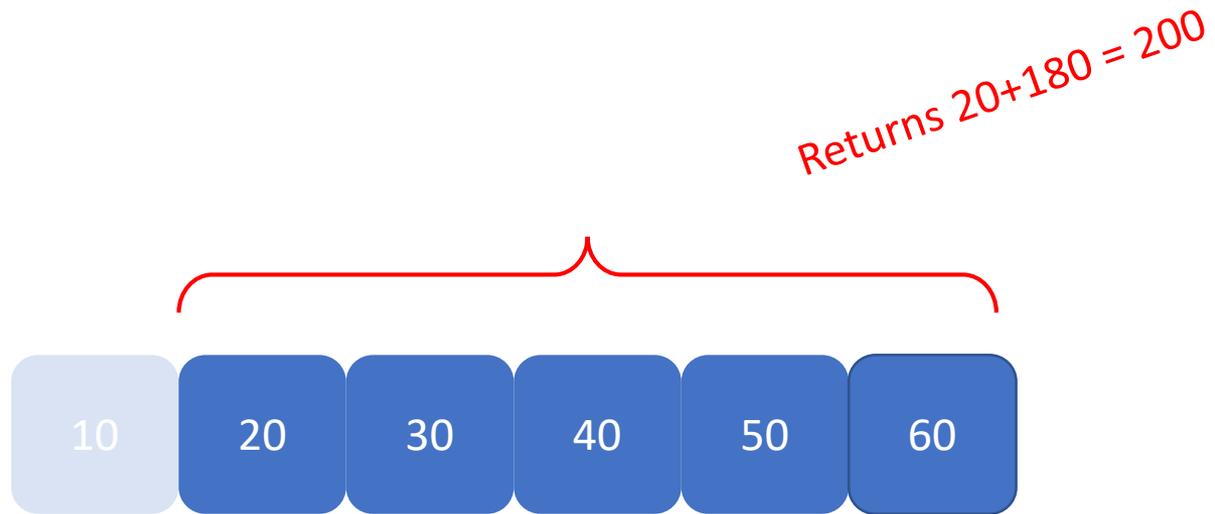

- Pass the sum back up the chain

# VISUALIZING LISTS as RECURSIVE

- Pass the sum back up the chain

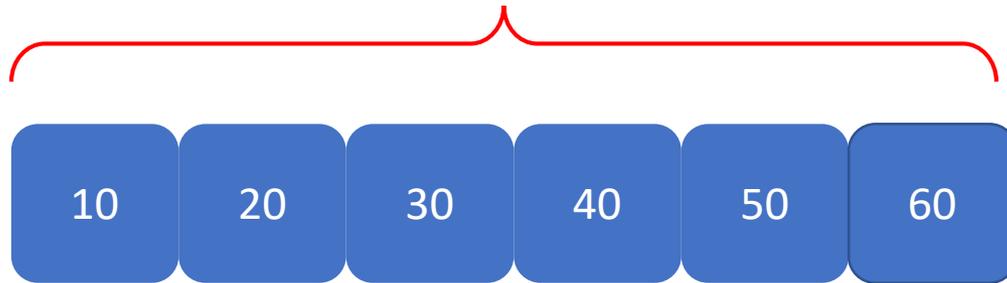

# VISUALIZING LISTS as RECURSIVE

- Pass the sum back up the chain

# VISUALIZING LISTS as RECURSIVE

Returns  $10+200 = 210$

- Pass the sum back up the chain

# SUM of LIST ELEMENTS: the PIECES

```
def total_recur(L):  
    if  
  
    else:
```

- Base case
- Recursive step

```
test = [30, 40, 50]  
print(total_recur(test))
```

# SUM of LIST ELEMENTS: the BASE CASE (one option)

```
def total_recur(L):  
    if L == []:  
        return 0  
    else:
```

```
test = [30, 40, 50]  
print(total_recur(test))
```

- What is the base case?
- One option:  
An **empty list** has sum 0

# SUM of LIST ELEMENTS: the BASE CASE (another option)

```
def total_recur(L):  
    if len(L) == 1:  
        return L[0]  
    else:  
  
test = [30, 40, 50]  
print(total_recur(test))
```

- What is the base case?
- Another option:  
A **list with one element**  
has a sum of that one  
element
- For example:  
L = [50]  
Returns:  
50

# SUM of LIST ELEMENTS: the RECURSIVE STEP

```
def total_recur(L):  
    if len(L) == 1:  
        return L[0]  
    else:  
        return L[0] + # something
```

```
test = [30, 40, 50]
```

```
print(total_recur(test))
```

- What is the recursive step?
- Need to get to the base case somehow
- Let's look at elements one at a time
- Extract the **first one** and grab its value
- For example:  
L = [30, 40, 50]  
Returns:  
30 + <something>

# SUM of LIST ELEMENTS

## RECURSIVE STEP will EVENTUALLY END

```
def total_recur(L):  
    if len(L) == 1:  
        return L[0]  
    else:  
        return L[0] + total_recur(L[1:])
```

```
test = [30, 40, 50]
```

```
print(total_recur(test))
```

- What is the recursive step?
- The function call finds the **sum of the remaining list elements**
- For example:  
L = [30, 40, 50]  
Returns:  
30 + total\_recur([40, 50])

# SUM of LIST ELEMENTS: TAKEAWAYS, [Python Tutor LINK](#)

```
def total_recur(L):  
    if len(L) == 1:  
        return L[0]  
    else:  
        return L[0] + total_recur(L[1:])
```

```
test = [30, 40, 50]  
print(total_recur(test))
```

- Notice:
- Every case in the function **returns something that is the same type**
  - Base case returns an int
  - Recursive step returns an int
- We need to **trust** that the recursive calls eventually do the right thing

# YOU TRY IT!

- Modify the code we wrote to return the total length of all strings inside L:

```
def total_len_recur(L):  
    if len(L) == 1:  
        return _____  
    else:  
        return _____  
  
test = ["ab", "c", "defgh"]  
print(total_len_recur(test)) # prints 8
```

# LOOKING for an ELEMENT in a LIST

# ANOTHER EXAMPLE:

## Is an ELEMENT in a LIST?

(careful with this implementation)

```
def in_list(L, e):  
    if len(L) == 1:  
        return L[0] == e  
    else:  
        return in_list(L[1:], e)
```

- Let's start by following the **same pattern** as the prev example
- Base case is when we have **one element**
  - Check if it's the one we are looking for
- Recursive step looks at the **remaining elements**
  - Grab the list from index 1 onward and look for e in it

## ANOTHER EXAMPLE:

Is an ELEMENT in a LIST?

(careful with this implementation) [Python Tutor](#)

```
def in_list(L, e):  
    if len(L) == 1:  
        return L[0] == e  
    else:  
        return in_list(L[1:], e)
```

```
test = [2, 5, 8, 1]
```

```
print(in_list(test, 1))
```

```
test = [2, 1, 5, 8]
```

```
print(in_list(test, 1))
```

- Test it out
- test = [2,5,8,1] and e=1 gives **True**
  - ok
- test = [2,1,5,8] and e=1 gives **False**
  - **Not ok!**
- It checks only if the last elem is the one we are looking for!

# ANOTHER EXAMPLE:

## Is an ELEMENT in a LIST?

(fix the implementation)

```
def in_list(L, e):  
    if len(L) == 1:  
        return L[0] == e  
    else:  
        # Check the first element  
        # before looking in the rest  
  
        return in_list(L[1:], e)
```

- Still want to look at elements one at a time
- Need to check whether the element we extracted is the one we are looking for **at each function call**

# ANOTHER EXAMPLE:

## Is an ELEMENT in a LIST?

(fix the implementation)

```
def in_list(L, e):  
    if len(L) == 1:  
        return L[0] == e  
    else:  
        if L[0] == e:  
            return True  
        else:  
            return in_list(L[1:], e)
```

- Still want to look at elements one at a time
- Add the **check in the recursive step**, before checking the rest of the list.

## ANOTHER EXAMPLE:

Is an ELEMENT in a LIST?

(test the implementation) [Python Tutor LINK](#)

```
def in_list(L, e):  
    if len(L) == 1:  
        return L[0] == e  
    else:  
        if L[0] == e:  
            return True  
        else:  
            return in_list(L[1:], e)
```

- Test it now
- test = [2,5,8,1] and e=1 gives True
  - ok
- test = [2,1,5,8] and e=1 gives True
  - ok
- test = [2,5,8] and e=1 gives False
  - ok

# ANOTHER EXAMPLE:

## Is an ELEMENT in a LIST?

(improve the implementation)

```
def in_list(L, e):  
    if len(L) == 0:  
        return False  
    elif L[0] == e:  
        return True  
    else:  
        return in_list(L[1:], e)
```

- Two cases that return L[0]
- Add case when L is empty
- **Simplify the code** to check the first element as another base case

# BIG IDEA

Each case (base cases, recursive step) must return the same type of object.

Remember that function returns build upon each other!

If the base case returns a bool and the recursive step returns an int, this gives a type mismatch error at runtime.

FLATTEN a LIST with  
ONLY ONE LEVEL of LIST  
ELEMENTS

FLATTEN a LIST CONTAINING LISTS of ints

e.g. `[[1, 2], [3, 4], [9, 8, 7]]`

gives `[1, 2, 3, 4, 9, 8, 7]`

```
def flatten(L):
```

```
    if len(L) == 1:
```

```
    else:
```

- Base case
- There is only **one element** in L
- For example:  
`[[2, 3, 4]]`

FLATTEN a LIST CONTAINING LISTS of ints

e.g. `[[1, 2], [3, 4], [9, 8, 7]]`

gives `[1, 2, 3, 4, 9, 8, 7]`

```
def flatten(L):
```

```
    if len(L) == 1:
```

```
        return L[0]
```

```
    else:
```

- Base case

- Return that element

- For example:

```
[[2, 3, 4]]
```

Returns:

```
[2, 3, 4]
```

FLATTEN a LIST CONTAINING LISTS of ints

e.g. `[[1, 2], [3, 4], [9, 8, 7]]`

gives `[1, 2, 3, 4, 9, 8, 7]`

```
def flatten(L):  
    if len(L) == 1:  
        return L[0]  
    else:  
        return L[0] + #something
```

- Recursive step
- Recall that + between two lists concatenates the elements into a new list
- Make a **new list containing the first element** and...

FLATTEN a LIST CONTAINING LISTS of ints

e.g. `[[1, 2], [3, 4], [9, 8, 7]]`

gives `[1, 2, 3, 4, 9, 8, 7]`

[Python Tutor LINK](#)

```
def flatten(L):
```

```
    if len(L) == 1:
```

```
        return L[0]
```

```
    else:
```

```
        return L[0] + flatten(L[1:])
```

- Recursive step
- ... **flatten the rest** of the remaining list
- For example:  
`[[1,2], [3,4], [9,8,7]]`  
**Returns:**  
`[1,2] +`  
`flatten([[3,4], [9,8,7]])`

# YOU TRY IT!

- Write a recursive function according to the specs below.

```
def in_list_of_lists(L, e):  
    """  
    L is a list whose elements are lists containing ints.  
    Returns True if e is an element within the lists of L  
    and False otherwise.  
    """  
    # your code here  
  
test = [[1,2], [3,4], [5,6,7]]  
print(in_list_of_lists(test, 0)) # prints False  
test = [[1,2], [3,4], [5,6,7]]  
print(in_list_of_lists(test, 3)) # prints True
```

# WHEN to USE RECURSION

- So far you should have some intuition for how to write recursive functions
- The problem is that so far you've been writing recursive version of functions that are usually easier to implement WITHOUT recursion :(
- So why learn recursion?
  - Some problems are very difficult to solve with iteration

# INTUITION for WHEN to use RECURSION

- Remember when we learned while loops?
- Remember when we tried to write a program that kept asking the user which way to go in the Lost Woods of Zelda?
- We did not know ahead of time how many times we needed to loop! (aka **how many levels of if/else we needed**)
- While loops kept iterating as long as some condition held true.

```
if <exit right>:  
  <set background to woods_background>  
  if <exit right>:  
    <set background to woods_background>  
    if <exit right>:  
      <set background to woods_background>  
      and so on and on and on...  
    else:  
      <set background to exit_background>  
  else:  
    <set background to exit_background>  
else:  
  <set background to exit_background>
```

# INTUITION for WHEN to use RECURSION

- In the list recursion examples so far, we knew how many levels we needed to iterate.
  - Either look at elems directly or in one level down
- **But lists can have elements that are lists, which can in turn have elements that are lists, which can in turn have elements that are lists, etc.**
- How can we use iteration to do these checks? It's hard.

```
for i in L:  
    if type(i) == list:  
        for j in i:  
            if type(j) == list:  
                for k in j:  
                    if type(k) == list:  
                        # and so on and on  
                    else:  
                        # do what you need to do  
                else:  
                    # do what you need to do  
            else:  
                # do what you need to do  
    else:  
        # do what you need to do  
# done with the loop over L and all its elements
```

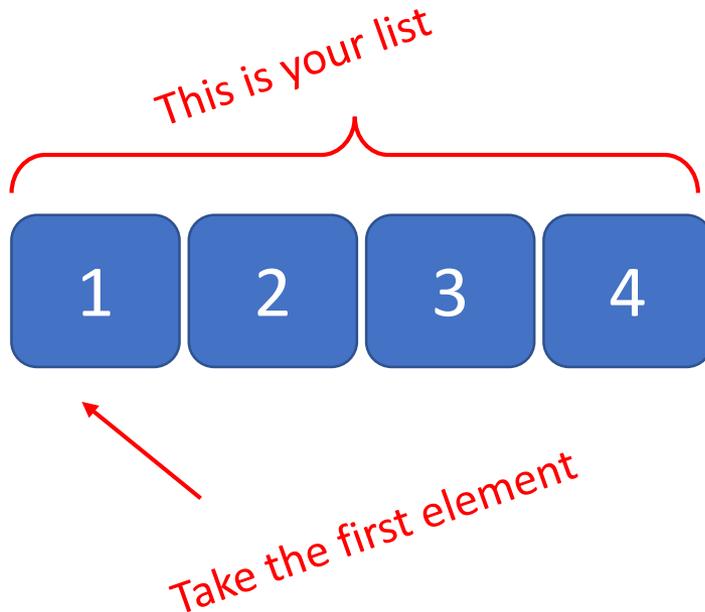

*You don't know how deep this goes*

# PROBLEMS that are NATURALLY RECURSIVE

- A file system
- Order of operations in a calculator
- Scooby Doo gang searching a haunted castle
- Bureaucracy

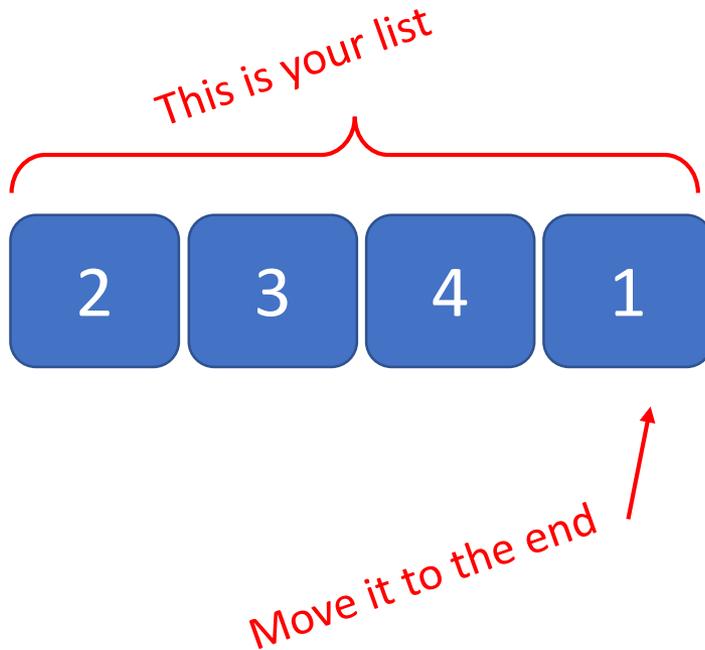

# LET'S SEE HOW TO GO FROM ONE LEVEL to MANY LEVELS (RECURSIVELY)

- Example: reverse a list's elements
- How to break up the problem into a smaller version of your same problem?

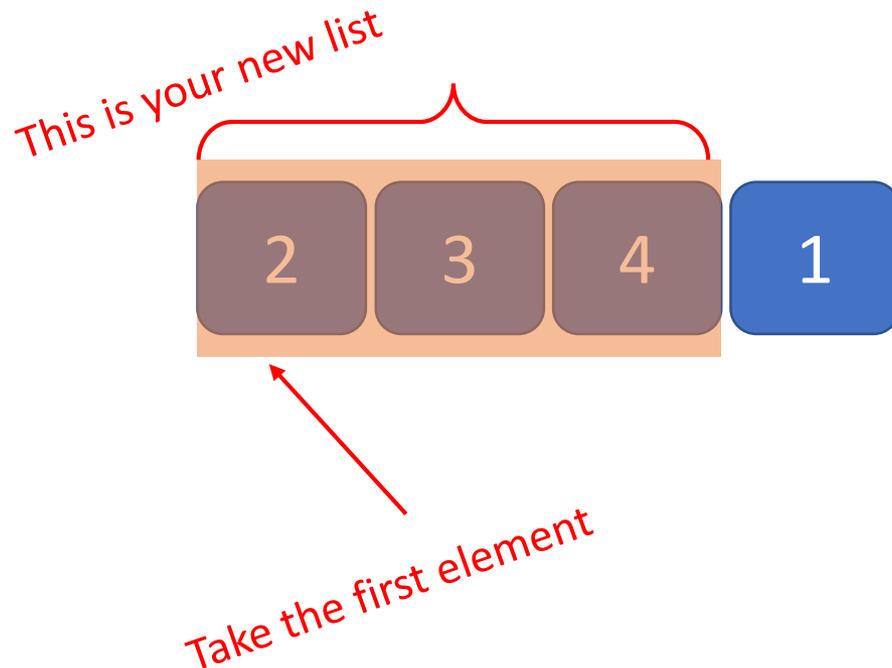

# LET'S SEE HOW TO GO FROM ONE LEVEL to MANY LEVELS (RECURSIVELY)

# LET'S SEE HOW TO GO FROM ONE LEVEL to MANY LEVELS (RECURSIVELY)

- Example: reverse a list's elements
- How to break up the problem into a smaller version of your same problem?

# REVERSE a LIST of ELEMENTS: TOP-LEVEL ONLY

```
def my_rev(L):  
    if len(L) == 1:  
  
    else:
```

- Base case

# REVERSE a LIST of ELEMENTS: TOP-LEVEL ONLY

```
def my_rev(L):  
    if len(L) == 1:  
        return L  
    else:
```

- Base case
- Reversing a list with one element is just that list.

# REVERSE a LIST of ELEMENTS: TOP-LEVEL ONLY

```
def my_rev(L):
```

```
    if len(L) == 1:
```

```
        return L
```

```
    else:
```

```
        return <something>
```

```
        + [[L[0]]]
```

*Make a list with  
one element*

- Recursive step
- Move element at index 0 to the end.
- Equivalent to **concatenating** something with that element
- For example:  
[10, 20, 30, 40]  
Returns:  
<something> + [10]

# REVERSE a LIST of ELEMENTS: TOP-LEVEL ONLY

```
def my_rev(L):  
    if len(L) == 1:  
        return L  
    else:  
        return my_rev(L[1:]) + [L[0]]
```

- Recursive step
- Solve the same problem, but on the **list containing all elements except the first one**
- For example:  
[10, 20, 30, 40]  
Returns:  
my\_rev([20, 30, 40]) + [10]

# REVERSE a LIST of ELEMENTS: TOP-LEVEL ONLY

[Python Tutor LINK](#)

```
def my_rev(L):  
    if len(L) == 1:  
        return L  
    else:  
        return my_rev(L[1:]) + [L[0]]
```

```
test = [1, 2, "abc"]  
print(my_rev(test))
```

```
test = [1, ['d'], ['e', ['f', 'g']]]  
print(my_rev(test))
```

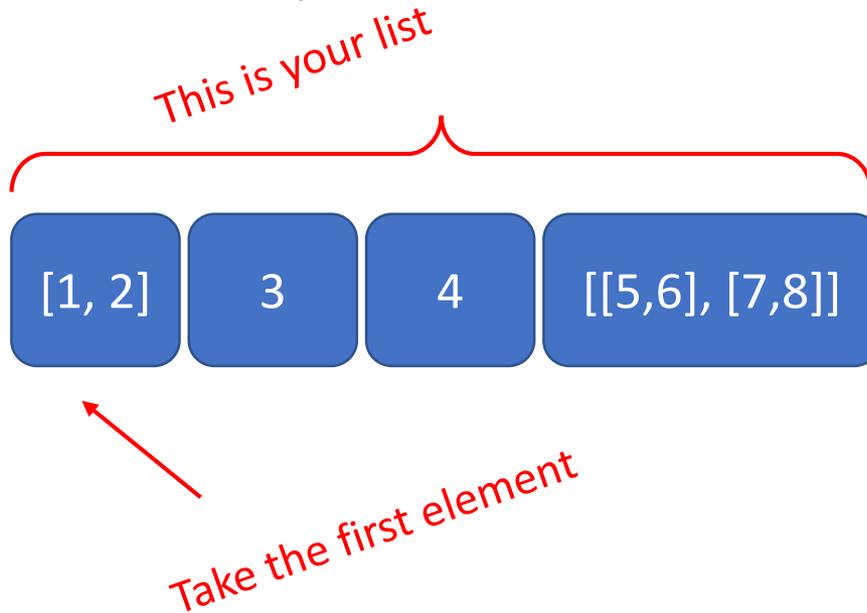

## • Test it

```
test = [1, 2, "abc"]  
  
# prints  
['abc', 2, 1]
```

```
test = [1, ['d'], ['e', ['f', 'g']]]  
  
# prints this, notice it  
# just reverses top-level elems  
[['e', ['f', 'g']], ['d'], 1]
```

# ALL ELEMENTS GET REVERSED

- Example: reverse all elements in all sublists
- Need to know whether we have an element or a list
  - Elements are put at the end, lists are reversed themselves

# ALL ELEMENTS GET REVERSED

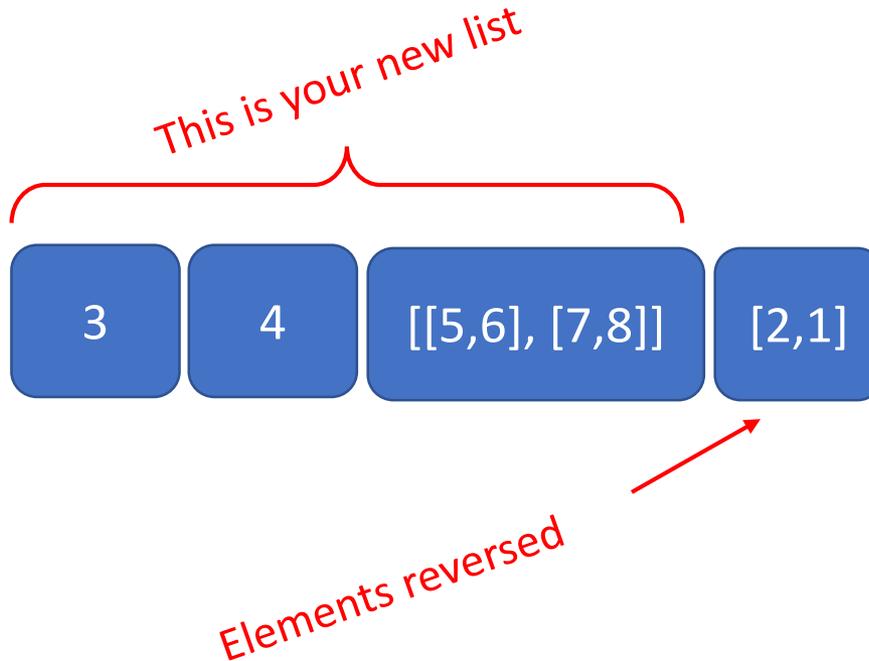

- If it's a list,

*Have to recursively  
reverse this one too!*

# ALL ELEMENTS GET REVERSED

- If it's a list,

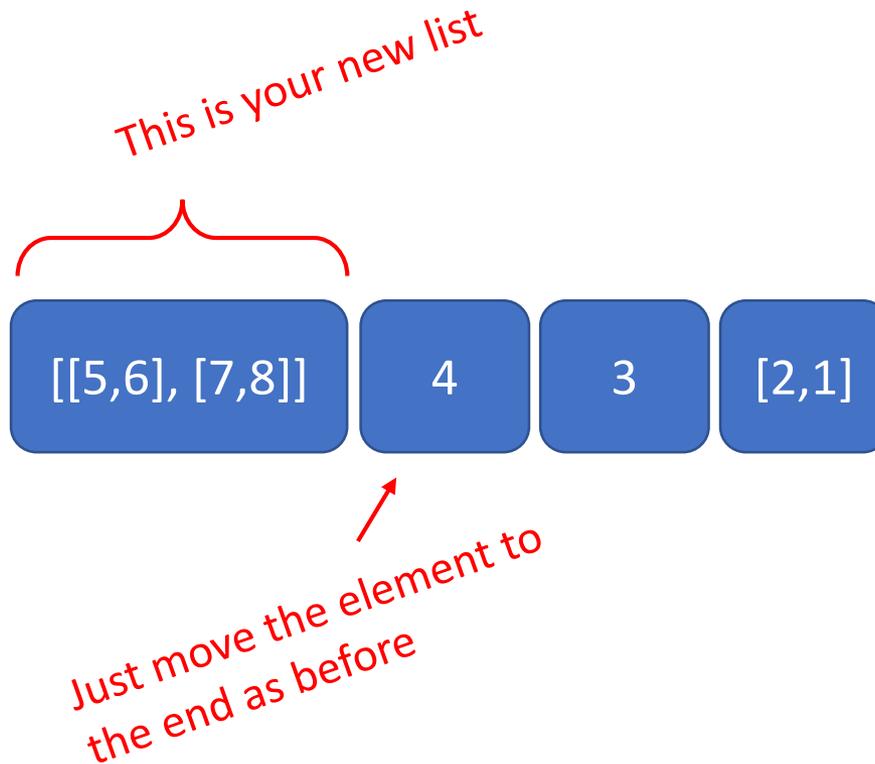

# ALL ELEMENTS GET REVERSED

- If it's **not** a list

# ALL ELEMENTS GET REVERSED

- And so on.

# ALL ELEMENTS GET REVERSED

- Lists within lists get reversed each

*Each sublist is reversed*

# ALL ELEMENTS GET REVERSED

- Lists within lists get reversed each

*And sublists within  
sublists are reversed*

# ALL ELEMENTS GET REVERSED

- Lists within lists get reversed each

*And sublists within  
sublists are reversed*

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED

```
def deep_rev(L):  
    if len(L) == 1:  
        if type(L[0]) != list:  
            # do something  
        else:  
            # do something
```

- Base case is NOT the same
- A single element can **either** be a
  - **Non-list:**
  - **List:**

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED

```
def deep_rev(L):  
    if len(L) == 1:  
        if type(L[0]) != list:  
            return L  
    else:  
        # do something
```

- Base case is NOT the same
- A single element can **either** be a
  - **Non-list**: it's just the list itself, like before
  - **List**:

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED

```
def deep_rev(L):  
    if len(L) == 1:  
        if type(L[0]) != list:  
            return L  
        else:  
            return [deep_rev(L[0])]  
```

Make a list with  
one element

- Base case is NOT the same
- A single element can **either** be a
  - **Non-list**: it's just the list itself, like before
  - **List**: Must reverse it!

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED

```
def deep_rev(L):  
    if len(L) == 1:  
        if type(L[0]) != list:  
            return L  
        else:  
            return [deep_rev(L[0])]  
    else:  
        if type(L[0]) != list:  
            # do something  
        else:  
            # do something
```

- **Recursive** step
- Extract the first element. It can **either** be a
  - **Non-list:**
  - **List:**

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED

```
def deep_rev(L):  
    if len(L) == 1:  
        if type(L[0]) != list:  
            return L  
        else:  
            return [deep_rev(L[0])]  
    else:  
        if type(L[0]) != list:  
            return deep_rev(L[1:]) + [[L[0]]]  
        else:  
            # do something
```

- **Recursive** step
- Extract the first element. It can **either** be a
  - **Non-list**: reverse the remaining elements and concatenate the result with the first element
  - **List**:

*Make a list with  
one element*

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED

```
def deep_rev(L):  
    if len(L) == 1:  
        if type(L[0]) != list:  
            return L  
        else:  
            return [deep_rev(L[0])]  
    else:  
        if type(L[0]) != list:  
            return deep_rev(L[1:]) + [L[0]]  
        else:  
            return deep_rev(L[1:]) + [deep_rev(L[0])]
```

- **Recursive** step
- Extract the first element. It can **either** be a
  - **Non-list**: reverse the remaining elements and concatenate the result with the first element
  - **List**: reverse the remaining elements and concatenate the result with the first element reversed (it's a list!) too

*Make a list with one element*

# REVERSE a LIST of ELEMENTS: ALL ELEMENTS GET REVERSED CLEANED UP CODE

```
def deep_rev(L):  
    if L == []:  
        return []  
    elif type(L[0]) != list:  
        return deep_rev(L[1:]) + [L[0]]  
    else:  
        return deep_rev(L[1:]) + [deep_rev(L[0])]
```

- Extract out the **empty list**
- Extract out **L[0]**

# BIG IDEA

Recursion procedure from this lecture can be applied to any indexable ordered sequence.

The same idea will work on problems involving strings.

The same idea will work on problems involving tuples.

# MAJOR RECURSION TAKEAWAYS

- Most problems are solved more **intuitively with iteration**
  - We show recursion on these to:
    - Show you a **different way of thinking** about the same problem (algorithm)
    - Show you **how to write a recursive function** (programming)
- Some problems have **nicer solutions with recursion**
  - If you recognize solving the same problem repeatedly, use recursion
- Tips
  - Every case in your recursive function **must return the same type of thing**  
i.e. don't have a base case `return []`  
and a recursive step `return len(L[0]) + recur(L[1:])`
  - Your function **doesn't have to be efficient on the first pass**
    - It's ok to have more than 1 base case
    - It's **ok to break down the problem** into many if/elifs
    - As long as you are **making progress** towards a base case recursively

# YOU TRY IT!

- I added many practice recursion questions in the .py file associated with this lecture, to prep for the quiz.
- 1) An exercise to implement a recursive function (**no** lists within lists etc.)
- 2) An exercise to implement a recursive function (**with** lists within lists within lists etc.)
- 3) Three buggy recursion implementations to fix.
